

Summery:

Part1:

Using too many filter and small polling stride will waste more time on training and it cause a bad learning result.

Use small filter will provide not enough information of the picture. So It also will not provide good result.

	A	B	C	D	E	F	G
1	Over 20 epoch						
2	NO modify	0.82					
3	stride	Acc	Filter	Acc			
4	4 4	0.808	12,12	0.79			
5	2 4	0.821	24,24	0.825			
6	1 1	0.194	48,48	0.203

Part2:

The save and load training get a good performance quickly(85% at epoch 10, which is better than the cnn-map model, with 81% acc over 50 epoch).

The pre-training will generate a good initialize of the parameter at lower level. And the shape and structure of the higher lever would not affect the initialization too much.

Part3:

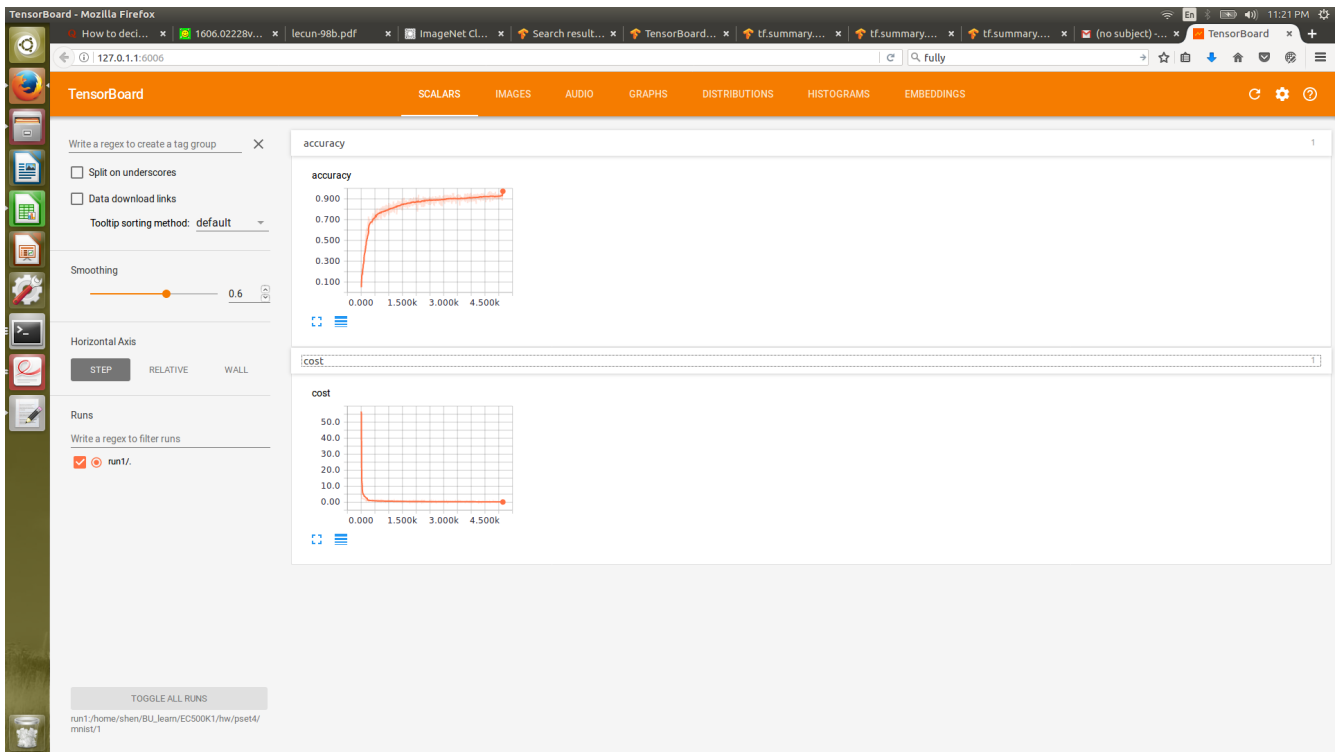

the normal training get 33% accuracy, the pre-load training get only 27.7%.

This result may reveal that the training parameter for different model is not compact.

Part4:

The Filters variable is hard to get.

I only plot the accuracy and cost.

Part 5:

I modify the model and the training file.

The model1 implement:

1. early stopping on training step
2. mini batch normalization, modify the batch size
3. two fully connected layer
4. dropped out on fully connected layer.
5. 2- layer pre-training 3 layer CNN

The model 2:

1. adjust the kernel and pooling unit size and number.
2. 4 layer CNN
3. MLP with more hidden unit

The original test accuracy is 82%, I have improve it to 88%.
